Research conducted under the supervision of
Prof. Marc Teboulle (Tel Aviv University)
and Prof. Shoham Sabach (Technion)

Goal and Outline

Develop and analyze two center-based clustering algorithms each with different distance-like function.

Outline

- Introduction to the clustering problem.
- Introduction to the convergence methodology.
- Clustering with the squared Euclidean norm: KPALM algorithm and its analysis.
- Clustering with the Euclidean norm: ε -KPALM algorithm and its analysis.
- Numerical results of the proposed algorithms.

The Clustering Problem

- Clustering is fundamental in fields such as machine learning, data mining, etc.
- The clustering problem focused a lot of research and there are many algorithms tackling it, such as k-means, Expectation-Maximization and others.
- It has been shown that the clustering problem is NP-hard.
- Let $\mathcal{A} = \{a^1, a^2, \dots, a^m\} \subset \mathbb{R}^n$ set of points, and $1 < k < m$ a given number of clusters.
- The goal is to partition the data \mathcal{A} into k subsets $\{\mathcal{C}^1, \mathcal{C}^2, \dots, \mathcal{C}^k\}$ called clusters.
- Each cluster \mathcal{C}^l is represented by its center $x^l \in \mathbb{R}^n$.
- The clustering problem is given by

$$(P_0) \quad \min_{x \in \mathbb{R}^{nk}} \left\{ F(x) := \sum_{i=1}^m \min_{1 \leq l \leq k} d(x^l, a^i) \right\},$$

with $d(\cdot, \cdot)$ being a distance-like function, such as the squared Euclidean norm.

Problem Reformulation

- Using the fact that

$$\min_{1 \leq l \leq k} u_l = \min \{ \langle u, v \rangle : v \in \Delta \},$$

where Δ is the simplex in \mathbb{R}^k , problem (P_0) can be transformed into

$$(P_1) \quad \min_{x \in \mathbb{R}^{nk}} \left\{ \sum_{i=1}^m \min_{w^i \in \Delta} \langle w^i, d^i(x) \rangle \right\},$$

with $d^i(x) = (d(x^1, a^i), d(x^2, a^i), \dots, d(x^k, a^i)) \in \mathbb{R}^k$, $i = 1, 2, \dots, m$.

- Replacing the constrain $w^i \in \Delta$ by adding the indicator function $\delta_{\Delta}(\cdot)$ results in

$$(P_2) \quad \min_{x \in \mathbb{R}^{nk}, w \in \mathbb{R}^{km}} \left\{ \sum_{i=1}^m \left(\langle w^i, d^i(x) \rangle + \delta_{\Delta}(w^i) \right) \right\},$$

where $w = (w^1, w^2, \dots, w^m) \in \mathbb{R}^{km}$.

- The final version is given by

$$(P) \quad \min \left\{ \sigma(z) := H(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\},$$

where $H(w, x) = \sum_{i=1}^m H^i(w, x) = \sum_{i=1}^m \langle w^i, d^i(x) \rangle$ and $G(w) = \sum_{i=1}^m \delta_{\Delta}(w^i)$.

Convergence Methodology: Goal and Definitions

Given:

Let $\sigma : \mathbb{R}^N \rightarrow \overline{\mathbb{R}}$ be a proper, lsc and bounded from below function.

$$(P) \quad \inf \left\{ \sigma(z) : z \in \mathbb{R}^N \right\}.$$

Suppose \mathcal{A} is a generic algorithm which generates a sequence $\{z^k\}_{k \in \mathbb{N}}$ via:

$$z^0 \in \mathbb{R}^N, z^{k+1} \in \mathcal{A}(z^k), k = 0, 1, \dots$$

Goal: To prove that **whole** $\{z^k\}_{k \in \mathbb{N}}$ **converges to a critical point of σ .**

Definition 1 (Limiting Subdifferential $\partial\sigma(x)$).

Let $\sigma : \mathbb{R}^d \rightarrow (-\infty, +\infty]$ be a proper and lower semicontinuous function.
The **(Limiting) Subdifferential** $\partial\sigma(x)$ is defined via:

$$\begin{aligned} u^* \in \partial\sigma(x) \quad \text{iff} \quad & (x_k, u_k^*) \rightarrow (x, u^*) \text{ s.t. } \sigma(x_k) \rightarrow \sigma(x) \text{ and} \\ & \sigma(u) \geq \sigma(x_k) + \langle u_k^*, u - x_k \rangle + o(\|u - x_k\|) \end{aligned}$$

- $x \in \mathbb{R}^d$ is a **critical point** of σ if $\partial\sigma(x) \ni 0$.
- The set of critical points of $\sigma \equiv \text{crit } \sigma$.
- $r \in \mathbb{R}$ is a **critical value** if $\exists x \in \text{crit } \sigma : \sigma(x) = r$.

KL property

Denote the following class of concave functions

$$\Phi_\eta = \left\{ \varphi \in C([0, \eta], \mathbb{R}_+) : \varphi \in C^1((0, \eta)), \varphi' > 0, \varphi(0) = 0 \right\}.$$

Definition 2 (Kurdyka-Łojasiewicz property).

Let $\sigma : \mathbb{R}^d \rightarrow (-\infty, +\infty]$ be proper and lower semicontinuous.

- (i) σ admits the KL property at $\bar{u} \in \text{dom } \partial\sigma := \{u \in \mathbb{R}^d : \partial\sigma \neq \emptyset\}$ if there exist $\eta \in (0, +\infty]$, a neighborhood U of \bar{u} and a function $\varphi \in \Phi_\eta$, such that for all

$$u \in U \cap \left\{ x \in \mathbb{R}^d : \sigma(\bar{u}) < \sigma(x) < \sigma(\bar{u}) + \eta \right\},$$

the following inequality holds

$$\varphi'(\sigma(u) - \sigma(\bar{u})) \text{dist}(0, \partial\sigma(u)) \geq 1,$$

where $\text{dist}(x, S) := \inf \{\|y - x\| : y \in S\}$ denotes the distance from $x \in \mathbb{R}^d$ to $S \subset \mathbb{R}^d$.

- (ii) If σ satisfy the KL property at each point of $\text{dom } \sigma$ then σ is called a *KL function*.

Semi-Algebraic Functions

Theorem 3 (Bolte-Daniilidis-Lewis (2006)).

Let $\sigma : \mathbb{R}^d \rightarrow \overline{\mathbb{R}}$ be a proper and lsc function. If σ is semi-algebraic then it satisfy the KL property at any point of $\text{dom } \sigma$.

Definition 4.

- (i) A subset S of \mathbb{R}^n is a real **semi-algebraic set** if there exists a finite number of real polynomial functions $g_{ij}, h_{ij} : \mathbb{R}^n \rightarrow \mathbb{R}$ such that

$$S = \bigcup_{j=1}^p \bigcap_{i=1}^q \{u \in \mathbb{R}^n : g_{ij}(u) = 0 \text{ and } h_{ij}(u) < 0\}.$$

- (ii) A function $\sigma : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ is called **semi-algebraic** if its graph

$$\{(u, t) \in \mathbb{R}^{n+1} : \sigma(u) = t\}$$

is a semi-algebraic subset of \mathbb{R}^{n+1} .

The Wealth of Semi-Algebraic Functions

- Real polynomial functions.
- Indicator functions of semi-algebraic sets.
- Finite sums and product of semi-algebraic functions.
- Composition of semi-algebraic functions.
- Sup/Inf type function, e.g., $\sup \{g(u, v) : v \in C\}$ is semi-algebraic when g is a semi-algebraic function and C a semi-algebraic set.
- The function $x \rightarrow \text{dist}(x, S)^2$ is semi-algebraic whenever S is a nonempty semi-algebraic subset of \mathbb{R}^n .
- $\|\cdot\|_0$ (counts the non-zero values) is semi-algebraic.
- $\|\cdot\|_p$ is semi-algebraic whenever $p > 0$ is rational.

In particular, for distance-like functions $d(x, y) = \|x - y\|^2$ and $d(x, y) = \|x - y\|$ the resulting clustering function defined in (P) is semi-algebraic.

Gradient-Like Descent Sequence

Definition 5.

Let $\sigma : \mathbb{R}^d \rightarrow (-\infty, +\infty]$ be a proper and lower semicontinuous function. A sequence $\{z^k\}_{k \in \mathbb{N}}$ is called a **gradient-like descent sequence** for σ if for all $k \in \mathbb{N}$ the following two conditions hold:

(C1) **Sufficient decrease property**: There exists a positive scalar ρ_1 such that

$$\rho_1 \|z^{k+1} - z^k\|^2 \leq \sigma(z^k) - \sigma(z^{k+1}).$$

(C2) **A subgradient lower bound for the iterates gap**:

- $\{z^k\}_{k \in \mathbb{N}}$ is bounded.
- There exists a positive scalar ρ_2 such that

$$\|w^{k+1}\| \leq \rho_2 \|z^{k+1} - z^k\|, \quad w^{k+1} \in \partial\sigma(z^{k+1}).$$

Theorem 6 (Bolte-Sabach-Teboulle (2014)).

Let $\sigma : \mathbb{R}^d \rightarrow (-\infty, \infty]$ be a proper, lower semicontinuous and semi-algebraic function with $\inf \sigma > -\infty$, and assume that $\{z^k\}_{k \in \mathbb{N}}$ is a gradient-like descent sequence for σ . If $\omega(z^0) \subset \text{crit}(\sigma)$ then the sequence $\{z^k\}_{k \in \mathbb{N}}$ converges to a critical point z^* of σ .

The Optimization Model

$$(M) \quad \text{minimize}_{x,y} \sigma(x, y) := f(x) + g(y) + H(x, y)$$

Assumption 1.

- (i) $f : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ and $g : \mathbb{R}^m \rightarrow \overline{\mathbb{R}}$ are proper and lsc functions.
- (ii) $H : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$ is a C^1 function.
- (iii) Partial gradients of H are Lipschitz continuous: $H(\cdot, y) \in C_{L(y)}^{1,1}$ and likewise $H(x, \cdot) \in C_L^{1,1}(x)$.

- **NO convexity** will be assumed in the objective or/and the constraints (built-in through f and g extended valued).

Let $\sigma : \mathbb{R}^n \rightarrow \overline{\mathbb{R}}$ be a proper and lsc function. Given $x \in \mathbb{R}^n$ and $t > 0$, the proximal map defined by:

$$\text{prox}_t^\sigma(x) := \operatorname{argmin} \left\{ \sigma(u) + \frac{t}{2} \|u - x\|^2 : u \in \mathbb{R}^n \right\}.$$

The Algorithm: Proximal Alternating Linearization Minimization (PALM)

- PALM blends alternating minimization with the classical proximal gradient over the two blocks (x, y) . This leads towards the following approximations:

$$\widehat{\sigma}(x, y^k) = \langle x - x^k, \nabla_x H(x^k, y^k) \rangle + \frac{c_k}{2} \|x - x^k\|^2 + f(x),$$

$$\widetilde{\sigma}(x^{k+1}, y) = \langle y - y^k, \nabla_y H(x^{k+1}, y^k) \rangle + \frac{d_k}{2} \|y - y^k\|^2 + g(y).$$

1. Initialization: start with any $(x^0, y^0) \in \mathbb{R}^n \times \mathbb{R}^m$.
2. For each $k = 0, 1, \dots$ generate a sequence $\{(x^k, y^k)\}_{k \in \mathbb{N}}$:

- 2.1. Take $\gamma_1 > 1$, set $c_k = \gamma_1 L_1(y^k)$ and compute

$$x^{k+1} \in \operatorname{argmin} \left\{ \widehat{\sigma}(x, y^k) : x \in \mathbb{R}^n \right\} = \operatorname{prox}_{c_k}^f \left(x^k - c_k^{-1} \nabla_x H(x^k, y^k) \right).$$

- 2.2. Take $\gamma_2 > 1$, set $d_k = \gamma_2 L_2(x^{k+1})$ and compute

$$y^{k+1} \in \operatorname{argmin} \left\{ \widetilde{\sigma}(x^{k+1}, y) : y \in \mathbb{R}^m \right\} = \operatorname{prox}_{d_k}^g \left(y^k - d_k^{-1} \nabla_y H(x^{k+1}, y^k) \right).$$

Main computational step: Computing prox of a nonconvex function.

KPALM Algorithm for Clustering with the Squared Norm Distance

Recalling the Clustering Problem for the squared norm distance:

$$(P) \quad \min \left\{ \sigma(z) := H(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\},$$

$$H(w, x) = \sum_{i=1}^m H^i(w, x) = \sum_{i=1}^m \langle w^i, d^i(x) \rangle = \sum_{i=1}^m \sum_{l=1}^k w_l^i \|x^l - a^i\|^2, \quad G(w) = \sum_{i=1}^m \delta_{\Delta}(w^i).$$

Inspired by PALM, we devise the KPALM algorithm, exploiting the specific structure of the model, namely

- The function $w \mapsto H(w, x)$, for fixed x , is linear and therefore there is no need to linearize it as suggested in PALM.

$$w^j(t+1) = \arg \min_{w^j \in \Delta} \left\{ \langle w^j, d^j(x(t)) \rangle + \frac{\alpha_j(t)}{2} \|w^j - w^j(t)\|^2 \right\}.$$

- The function $x \mapsto H(w, x)$, for fixed w , is quadratic and convex. Hence, there is no need to add a proximal term as suggested in PALM.

$$x(t+1) = \operatorname{argmin} \left\{ H(w(t+1), x) \mid x \in \mathbb{R}^{nk} \right\}.$$

KPALM Algorithm for Clustering with the Squared Norm Distance

KPALM performs alternation between the cluster assignment and the center update steps. Solving the previously described minimization sub-problems yields the KPALM algorithm.

(1) Initialization: $z(0) = (w(0), x(0)) \in \Delta^m \times \mathbb{R}^{nk}$.

(2) General step ($t = 0, 1, \dots$):

(2.1) Cluster assignment: choose certain $\alpha_i(t) > 0$, $i = 1, 2, \dots, m$, and compute

$$w^i(t+1) = P_{\Delta} \left(w^i(t) - \frac{d^i(x(t))}{\alpha_i(t)} \right).$$

(2.2) Center update: for each $l = 1, 2, \dots, k$ compute

$$x^l(t+1) = \frac{\sum_{i=1}^m w_l^i(t+1) a^i}{\sum_{i=1}^m w_l^i(t+1)}.$$

- Setting $\alpha_i(t) = 0$ yields the popular k-means algorithm.

KPALM Analysis

- Boundedness: $w^i(t) \in \Delta$ and

$$x^l(t) = \frac{\sum_{i=1}^m w_i^j(t) a^j}{\sum_{i=1}^m w_i^j(t)} = \sum_{i=1}^m \left(\frac{w_i^j(t)}{\sum_{j=1}^m w_i^j(t)} \right) a^j \in \text{Conv}(\mathcal{A}).$$

- KL Property: H is a weighted sum of squared Euclidean norms hence semi-algebraic, and Δ is semi-algebraic set, thus $\delta_\Delta(\cdot)$ is semi-algebraic, and in turn σ since it is sum of these functions.

Assumption 2.

- (i) *The chosen sequences of parameters $\{\alpha_i(t)\}_{t \in \mathbb{N}}$, $1 \leq i \leq m$, are bounded: $0 < \underline{\alpha}_i \leq \alpha_i(t) \leq \bar{\alpha}_i < \infty$, $\forall t \in \mathbb{N}$.*
- (ii) *For all $t \in \mathbb{N}$ there exists $\underline{\beta} > 0$ such that $2 \min_{1 \leq l \leq k} \sum_{i=1}^m w_i^l(t) := \beta(w(t)) \geq \underline{\beta}$.*

Denote $\underline{\alpha} = \min_{1 \leq i \leq m} \underline{\alpha}_i$ and $\bar{\alpha} = \max_{1 \leq i \leq m} \bar{\alpha}_i$.

KPALM Sufficient Decrease Proof

Since $x \mapsto H(w, x) = \sum_{l=1}^k \sum_{i=1}^m w_l^i \|x^l - a^i\|^2$ is C^2 , and its Hessian is given by

$$\nabla_{x^j} \nabla_{x^l} H(w, x) = \begin{cases} 0 & \text{if } j \neq l, \quad 1 \leq j, l \leq k, \\ 2 \sum_{i=1}^m w_l^i & \text{if } j = l, \quad 1 \leq j, l \leq k, \end{cases}$$

then it is strongly convex with parameter $\beta(w)$, whenever $\beta(w) = 2 \min_{1 \leq l \leq k} \sum_{i=1}^m w_l^i > 0$.

Assumption 2(ii) ensures that $x \mapsto H(w(t), x)$ is strongly convex with parameter $\beta(w(t))$, hence

$$\begin{aligned} H(w(t+1), x(t)) - H(w(t+1), x(t+1)) &\geq \\ &\geq \langle \nabla_x H(w(t+1), x(t+1)), x(t) - x(t+1) \rangle + \frac{\beta(w(t))}{2} \|x(t) - x(t+1)\|^2 \\ &= \frac{\beta(w(t))}{2} \|x(t+1) - x(t)\|^2 \\ &\geq \frac{\beta}{2} \|x(t+1) - x(t)\|^2, \end{aligned}$$

where the equality follows from $\nabla_x H(w(t+1), x(t+1)) = 0$.

KPALM Sufficient Decrease Proof-Contd.

From the w update step we derive

$$\begin{aligned} H^i(w(t+1), x(t)) + \frac{\alpha_i(t)}{2} \|w^i(t+1) - w^i(t)\|^2 &= \\ &= \langle w^i(t+1), d^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i(t+1) - w^i(t)\|^2 \\ &\leq \langle w^i(t), d^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i(t) - w^i(t)\|^2 \\ &= \langle w^i(t), d^i(x(t)) \rangle = H^i(w(t), x(t)). \end{aligned}$$

Summing the last inequality over all $1 \leq i \leq m$ yields

$$\frac{\underline{\alpha}}{2} \|w(t+1) - w(t)\|^2 \leq H(w(t), x(t)) - H(w(t+1), x(t))$$

Set $\rho_1 = \frac{1}{2} \min \{\underline{\alpha}, \underline{\beta}\}$, by combining the sufficient decrease in x and w variables we get

$$\begin{aligned} \rho_1 \|z(t+1) - z(t)\|^2 &= \rho_1 \left(\|w(t+1) - w(t)\|^2 + \|x(t+1) - x(t)\|^2 \right) \leq \\ &\leq [H(w(t), x(t)) - H(w(t+1), x(t))] + [H(w(t+1), x(t)) - H(w(t+1), x(t+1))] \\ &= H(z(t)) - H(z(t+1)) = \sigma(z(t)) - \sigma(z(t+1)). \end{aligned}$$

KPALM Subgradient Lower Bound The Iterates Gap Proof

Recalling the steps of KPLAM algorithm:

$$w^i(t+1) = \arg \min_{w^i \in \Delta} \left\{ \langle w^i, d^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i - w^i(t)\|^2 \right\} \quad (1)$$

$$x(t+1) = \operatorname{argmin} \left\{ H(w(t+1), x) \mid x \in \mathbb{R}^{nk} \right\} \quad (2)$$

The subgradient of σ is given by

$$\partial \sigma = \nabla H + \partial G = \left(\left(\nabla_{w^i} H^i + \partial_{w^i} \delta_{\Delta} \right)_{i=1,2,\dots,m}, \nabla_x H \right).$$

Evaluating the last relation at $z(t+1)$ and using (2)

$$\begin{aligned} \partial \sigma(z(t+1)) &= \left(\left(d^i(x(t+1)) + \partial_{w^i} \delta_{\Delta}(w^i(t+1)) \right)_{i=1,2,\dots,m}, \nabla_x H(z(t+1)) \right) \\ &= \left(\left(d^i(x(t+1)) + \partial_{w^i} \delta_{\Delta}(w^i(t+1)) \right)_{i=1,2,\dots,m}, \mathbf{0} \right). \end{aligned}$$

The optimality condition of $w^i(t+1)$ (see (1)), implies that there exists $u^i(t+1) \in \partial \delta_{\Delta}(w^i(t+1))$ such that

$$d^i(x(t)) + \alpha_i(t) (w^i(t+1) - w^i(t)) + u^i(t+1) = \mathbf{0}.$$

KPALM Subgradient Lower Bound The Iterates Gap Proof-Contd.

Setting $\gamma(t+1) := \left((d^i(x(t+1)) + u^i(t+1))_{i=1,2,\dots,m}, \mathbf{0} \right) \in \partial\sigma(z(t+1))$.

$$\begin{aligned}\|\gamma(t+1)\| &\leq \sum_{i=1}^m \left\| d^i(x(t+1)) - d^i(x(t)) - \alpha_i(t) (w^i(t+1) - w^i(t)) \right\| \\ &\leq \sum_{i=1}^m \left\| d^i(x(t+1)) - d^i(x(t)) \right\| + \sum_{i=1}^m \alpha_i(t) \left\| w^i(t+1) - w^i(t) \right\| \\ &\leq \sum_{i=1}^m 4M \|x(t+1) - x(t)\| + m\bar{\alpha} \|z(t+1) - z(t)\| \\ &\leq m(4M + \bar{\alpha}) \|z(t+1) - z(t)\|,\end{aligned}$$

where the third inequality follows from the inequality

$$\|d^i(x(t+1)) - d^i(x(t))\| \leq 4M \|x(t+1) - x(t)\|, \quad \forall i = 1, 2, \dots, m, \quad t \in \mathbb{N},$$

with $M = \max_{1 \leq i \leq m} \|a^i\|$ and the result follows with $\rho_2 = m(4M + \bar{\alpha})$.

ε -KPALM Algorithm for Clustering with the Norm Distance

Recalling the Clustering Problem for the Euclidean norm distance:

$$(P) \quad \min \left\{ \sigma(z) := H(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\},$$

$$H(w, x) = \sum_{i=1}^m H^i(w, x) = \sum_{i=1}^m \langle w^i, d^i(x) \rangle = \sum_{i=1}^m \sum_{l=1}^k w_l^i \|x^l - a^i\|, \quad G(w) = \sum_{i=1}^m \delta_{\Delta}(w^i).$$

- H is not smooth, hence PALM cannot be applied as is. Therefore approximating:

$$H_{\varepsilon}(w, x) = \sum_{i=1}^k H_{\varepsilon}^i(w, x) = \sum_{i=1}^k \sum_{l=1}^m w_l^i (\|x^l - a^i\|^2 + \varepsilon^2)^{1/2},$$

- This leads towards the following approximation of the Clustering Problem

$$(P_{\varepsilon}) \quad \min \left\{ \sigma_{\varepsilon}(z) := H_{\varepsilon}(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\}.$$

- Also $d_{\varepsilon}^i(x)$ is the smoothed version of $d^i(x)$, whose $1 \leq l \leq k$ coordinate is $(\|x^l - a^i\|^2 + \varepsilon^2)^{1/2}$.

Lemma 7 (Closeness of smooth).

For any $(w, x) \in \Delta^m \times \mathbb{R}^{nk}$ and $\varepsilon > 0$ the following relations hold true

$$H(w, x) \leq H_{\varepsilon}(w, x) \leq H(w, x) + m\varepsilon.$$

ε -KPALM Algorithm for Clustering with the Norm Distance

- With respect to w we apply the same step as in KPALM:

$$w^i(t+1) = \arg \min_{w^i \in \Delta} \left\{ \langle w^i, d_\varepsilon^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i - w^i(t)\|^2 \right\}.$$

- With respect to x we tackle the subproblem differently than in KPALM, linearizing the function $x \rightarrow H(w, \cdot)$, for fixed w , and adding a regularizing term

$$x^l(t+1) = \operatorname{argmin}_{x^l} \left\{ \langle x^l - x^l(t), \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \rangle + \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l - x^l(t)\|^2 \right\},$$

where

$$L_\varepsilon^l(w(t+1), x(t)) := \sum_{i=1}^m \frac{w_i^l(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}}, \quad \forall l = 1, 2, \dots, k.$$

(1) Initialization: $z(0) = (w(0), x(0)) \in \Delta^m \times \mathbb{R}^{nk}$.

(2) General step ($t = 0, 1, \dots$):

(2.1) Cluster assignment: choose certain $\alpha_i(t) > 0$, $i = 1, 2, \dots, m$, and compute

$$w^i(t+1) = P_\Delta \left(w^i(t) - \frac{d_\varepsilon^i(x(t))}{\alpha_i(t)} \right).$$

(2.2) Center update: for each $l = 1, 2, \dots, k$ compute

$$x^l(t+1) = x^l(t) - \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \nabla_{x^l} H_\varepsilon(w(t+1), x(t)).$$

ε -KPALM Analysis

- Boundedness: $w^i(t) \in \Delta$ and

$$\begin{aligned} x^l(t+1) &= x^l(t) - \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \\ &= x^l(t) - \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \sum_{i=1}^m w_i^l(t+1) \cdot \frac{x^l(t) - a^i}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \\ &= \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \sum_{i=1}^m \left(\frac{w_i^l(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \right) a^i \in \text{Conv}(\mathcal{A}). \end{aligned}$$

- KL Property is straightforward from the Semi-Algebraicity of the involved functions.

Motivated by the recent work on Weber problem [Beck-Sabach\(2015\)](#), we develop several auxiliary results. We define the function $f_\varepsilon : \mathbb{R}^n \rightarrow \mathbb{R}$ by

$$f_\varepsilon(x) = \sum_{i=1}^m v_i (\|x - a^i\|^2 + \varepsilon^2)^{1/2},$$

$v^i \in \mathbb{R}_+$ fixed weights. We also need the following auxiliary function $h_\varepsilon : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$h_\varepsilon(x, y) = \sum_{i=1}^m \frac{v_i (\|x - a^i\|^2 + \varepsilon^2)}{(\|y - a^i\|^2 + \varepsilon^2)^{1/2}}.$$

Finally we introduce the following modulus, $L_\varepsilon : \mathbb{R}^n \rightarrow \mathbb{R}$ defined by

$$L_\varepsilon(x) = \sum_{i=1}^m \frac{v_i}{(\|x - a^i\|^2 + \varepsilon^2)^{1/2}}.$$

Properties of the Auxiliary Functions h_ε and f_ε

Lemma 8.

The following properties of h_ε hold.

(i) For any $y \in \mathbb{R}^n$,

$$h_\varepsilon(y, y) = f_\varepsilon(y).$$

(ii) For any $x, y \in \mathbb{R}^n$,

$$h_\varepsilon(x, y) \geq 2f_\varepsilon(x) - f_\varepsilon(y).$$

(iii) For any $x, y \in \mathbb{R}^n$,

$$f_\varepsilon(x) \leq f_\varepsilon(y) + \langle \nabla f_\varepsilon(y), x - y \rangle + \frac{L_\varepsilon(y)}{2} \|x - y\|^2.$$

Lemma 9.

For all $y, z \in \mathbb{R}^n$ the following statement holds true

$$\|\nabla f_\varepsilon(y) - \nabla f_\varepsilon(z)\| \leq \frac{2L_\varepsilon(z)L_\varepsilon(y)}{L_\varepsilon(z) + L_\varepsilon(y)} \|z - y\|.$$

Preliminaries for Sufficient Decrease Proof

Proposition 1 (Bounds for L_ε^I).

Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by ε -KPALM.

(i) Denote $d_{\mathcal{A}} = \text{diam}(\text{Conv}(\mathcal{A}))$. For all $t \in \mathbb{N}$ and $l = 1, 2, \dots, k$ we have

$$L_\varepsilon^l(w(t+1), x(t)) \geq \frac{\underline{\beta}}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}}.$$

(ii) For all $t \in \mathbb{N}$ and $l = 1, 2, \dots, k$ we have

$$L_\varepsilon^l(w(t+1), x(t)) \leq \frac{m}{\varepsilon}.$$

Proof.

(i) Using $\underline{\beta}$ as in Assumption 2(ii) and the fact that $x^l(t) \in \text{Conv}(\mathcal{A})$, we obtain

$$L_\varepsilon^l(w(t+1), x(t)) = \sum_{i=1}^m \frac{w_i^j(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \geq \frac{\sum_{i=1}^m w_i^j(t+1)}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}} \geq \frac{\underline{\beta}}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}},$$

where the first inequality follows from the fact that $\|x^l(t) - a^i\| \leq d_{\mathcal{A}}$.

(ii) Since $w(t+1) \in \Delta^m$ we have

$$L_\varepsilon^l(w(t+1), x(t)) = \sum_{i=1}^m \frac{w_i^j(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \leq \sum_{i=1}^m \frac{1}{\varepsilon} = \frac{m}{\varepsilon}.$$

Preliminaries for Sufficient Decrease Proof

Proposition 2.

Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by ε -KPALM. Then, for all $t \in \mathbb{N}$, we have

$$H_\varepsilon(w(t+1), x(t+1)) \leq H_\varepsilon(w(t+1), x(t)) + \langle \nabla_x H_\varepsilon(w(t+1), x(t)), x(t+1) - x(t) \rangle + \sum_{l=1}^k \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l(t+1) - x^l(t)\|^2.$$

Proof.

By definition of f_ε , using the weights $v_i = w_i^j(t+1)$, we obtain

$$H_\varepsilon^l(w(t+1), x(t)) = f_\varepsilon(x^l(t)).$$

Therefore, by applying Lemma 8(iii) with $x = x^l(t+1)$ and $y = x^l(t)$, we get

$$H_\varepsilon^l(w(t+1), x(t+1)) \leq H_\varepsilon^l(w(t+1), x(t)) + \langle \nabla_{x^l} H_\varepsilon^l(w(t+1), x(t)), x(t+1) - x(t) \rangle + \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l(t+1) - x^l(t)\|^2.$$

Summing the last inequality over $l = 1, 2, \dots, k$, yields

$$H_\varepsilon(w(t+1), x(t+1)) \leq H_\varepsilon(w(t+1), x(t)) + \sum_{l=1}^k \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l(t+1) - x^l(t)\|^2 + \sum_{l=1}^k \langle \nabla_{x^l} H_\varepsilon(w(t+1), x(t)), x^l(t+1) - x^l(t) \rangle.$$

The result follows by replacing the last term with the following compact form

$$\sum_{l=1}^k \langle \nabla_{x^l} H_\varepsilon(w(t+1), x(t)), x^l(t+1) - x^l(t) \rangle = \langle \nabla_x H_\varepsilon(w(t+1), x(t)), x(t+1) - x(t) \rangle.$$

ε -KPALM Sufficient Decrease Proof

With respect to w ε -KPALM sufficient decrease is similar to that of KPALM, which yields

$$\frac{\underline{\alpha}}{2} \|w(t+1) - w(t)\|^2 \leq H_\varepsilon(w(t), x(t)) - H_\varepsilon(w(t+1), x(t)). \quad (1)$$

Applying Proposition 2 with the center update step in ε -KPALM we get for all $t \in \mathbb{N}$ that

$$\begin{aligned} H_\varepsilon(w(t+1), x(t)) - H_\varepsilon(w(t+1), x(t+1)) &\geq \sum_{l=1}^k \frac{L'_\varepsilon(w(t+1), x(t))}{2} \|x^l(t+1) - x^l(t)\|^2 \\ &\geq \frac{\underline{\beta}}{(d_A^2 + \varepsilon^2)^{1/2}} \sum_{l=1}^k \|x^l(t+1) - x^l(t)\|^2 \\ &\geq \frac{\underline{\beta}}{(d_A^2 + \varepsilon^2)^{1/2}} \|x(t+1) - x(t)\|^2, \quad (2) \end{aligned}$$

where the second inequality follows from Proposition 1(i).

Set $\rho_1 = \frac{1}{2} \min \left\{ \underline{\alpha}, \underline{\beta} / (d_A^2 + \varepsilon^2)^{1/2} \right\}$. Summing (1) and (2) yields

$$\begin{aligned} \rho_1 \|z(t+1) - z(t)\|^2 &= \rho_1 \left(\|w(t+1) - w(t)\|^2 + \|x(t+1) - x(t)\|^2 \right) \\ &\leq [H_\varepsilon(w(t), x(t)) - H_\varepsilon(w(t+1), x(t))] + [H_\varepsilon(w(t+1), x(t)) - H_\varepsilon(w(t+1), x(t+1))] \\ &= H_\varepsilon(z(t)) - H_\varepsilon(z(t+1)) \\ &= \sigma_\varepsilon(z(t)) - \sigma_\varepsilon(z(t+1)). \end{aligned}$$

ε -KPALM Subgradient Lower Bound The Iterates Gap Proof

Repeating the steps of the proof in the case of KPALM yields that

$$\gamma(t+1) := \left((d_\varepsilon^i(x(t+1)) + u^i(t+1))_{i=1,\dots,m}, \nabla_x H_\varepsilon(w(t+1), x(t+1)) \right) \in \partial \sigma_\varepsilon(z(t+1)), \quad (3)$$

where $u^i(t+1) \in \partial \delta_\Delta(w^i(t+1))$, $i = 1, 2, \dots, m$.

Writing the optimality condition of the cluster assignment step yields

$$d_\varepsilon^i(x(t)) + \alpha_i(t) (w^i(t+1) - w^i(t)) + u^i(t+1) = \mathbf{0}. \quad (4)$$

Plugging (4) into (3), and taking the norm yields

$$\begin{aligned} \|\gamma(t+1)\| &\leq \sum_{i=1}^m \|d_\varepsilon^i(x(t+1)) - d_\varepsilon^i(x(t)) - \alpha_i(t) (w^i(t+1) - w^i(t))\| + \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \\ &\leq \sum_{i=1}^m \|d_\varepsilon^i(x(t+1)) - d_\varepsilon^i(x(t))\| + \sum_{i=1}^m \alpha_i(t) \|w^i(t+1) - w^i(t)\| + \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \\ &\leq \frac{md_{\mathcal{A}}}{\varepsilon} \|x(t+1) - x(t)\| + \bar{\alpha} \sqrt{m} \|w(t+1) - w(t)\| + \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\|, \end{aligned}$$

where the last inequality follows from the inequality

$$\|d_\varepsilon^i(x) - d_\varepsilon^i(y)\| \leq \frac{d_{\mathcal{A}}}{\varepsilon} \|x - y\|, \text{ whenever } x^l, y^l \in \text{Conv}(\mathcal{A}) \quad \forall 1 \leq l \leq k,$$

and the fact that $\bar{\alpha} = \max_{1 \leq i \leq m} \bar{\alpha}_i$.

ε -KPALM Subgradient Lower Bound The Iterates Gap Proof-Contd.

It is sufficient to show that $\|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \leq c\|x(t+1) - x(t)\|$, for some constant $c > 0$. First, note that for fixed $w \in \Delta^m$ and any $x \in \mathbb{R}^{nk}$ the following relation holds

$$\nabla_{x^l} H_\varepsilon(w, x) = \nabla f_\varepsilon(x^l), \quad \forall l = 1, 2, \dots, k. \quad (5)$$

Now, for all $l = 1, 2, \dots, k$, we have

$$\begin{aligned} \nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) &= \nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) - \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) + \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \\ &= \nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) - \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) + L'_\varepsilon(w(t+1), x(t)) (x^l(t) - x^l(t+1)), \end{aligned}$$

where the last equality follows from center update step. Therefore,

$$\begin{aligned} \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| &\leq \sum_{l=1}^k \|\nabla_{x^l} H_\varepsilon(w(t+1), x(t+1))\| \\ &\leq \sum_{l=1}^k L'_\varepsilon(w(t+1), x(t)) \|x^l(t+1) - x^l(t)\| + \sum_{l=1}^k \|\nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) - \nabla_{x^l} H_\varepsilon(w(t+1), x(t))\| \\ &\leq \frac{m}{\varepsilon} \sum_{l=1}^k \|x^l(t+1) - x^l(t)\| + \sum_{l=1}^k \gamma^l(t) \|x^l(t+1) - x^l(t)\|, \quad (*) \end{aligned}$$

where the last inequality follows from Lemma 1(ii) and Theorem 9 combined with the (5) observation using

$$\gamma^l(t) = \frac{2L'_\varepsilon(w(t+1), x(t))L'_\varepsilon(w(t+1), x(t+1))}{L'_\varepsilon(w(t+1), x(t)) + L'_\varepsilon(w(t+1), x(t+1))}, \quad l = 1, 2, \dots, k.$$

Numerical Results: The Squared Norm

- Initialization issues: randomly picking k data points as starting centers vs. k-means++.
- Comparison of the objective function values performed on the Iris dataset for squared norm algorithms

- In the squared Euclidean setting, KPALM achieves lower objective function values than k-means. When using a more sophisticated initialization step, such as the one in k-means++, then k-means++ and KPALM++ achieve similar objective function values.
- k-means needs less number of iterations than KPALM to reach a certain precision.

Numerical Results: The Squared Norm

- Comparison of the objective function values performed on the Iris dataset for KPALM algorithm with different α parameter updates.

- It is preferable to use dynamic update of $\alpha(t)$ parameter to achieve a faster convergence, both in KPALM and ϵ -KPALM. Example for suitable choices can be $\alpha(t) = \text{diam}(\mathcal{A})/t$ and $\alpha(t) = \text{diam}(\mathcal{A})/2^t$.

Numerical Results: Squared Norm Algorithms vs. ε -KPALM

- Generated two synthetic datasets, each 300 points

(a) Dense Gaussians

(b) Sparse Gaussians

- Compared the resulting clustering using metrics, such as **Variation of Information** defined by: $VI(\mathcal{C}^1, \mathcal{C}^2) := - \sum_{i,j} r_{i,j} [\log(r_{i,j}/p_i) + \log(r_{i,j}/q_j)]$, where $\mathcal{C}^1 = \{C_1^1, C_2^1, \dots, C_k^1\}$ and $\mathcal{C}^2 = \{C_1^2, C_2^2, \dots, C_l^2\}$ are two clusterings of \mathcal{A} , and $m = |\mathcal{A}|$, $p_i = |C_i^1|/m$, $q_j = |C_j^2|/m$, $r_{i,j} = |C_i^1 \cap C_j^2|/m$.

Numerical Results: Squared Norm Algorithms vs. ε -KPALM

(a) Dense Gaussians metrics comparison

(b) Sparse Gaussians metrics comparison

- When the convex hulls of the desired clusters are mutually exclusive, algorithms which solve the clustering problem with the squared Euclidean distance are preferable to ε -KPALM.
- In datasets with outliers, the clustering obtained with ε -KPALM is more similar to the desired clustering, in terms of clustering metrics, than the clusterings obtained via the squared Euclidean algorithms. Therefore, as expected, for data with outliers, the choice of a norm instead of the squared norm is a more natural choice, and the ε -KPALM algorithm appears to be a promising algorithm to handle such data.
