

1 The Clustering Problem

Let $\mathcal{A} = \{a^1, a^2, \dots, a^m\}$ be a given set of points in \mathbb{R}^n , and let $1 < k < m$ be a fixed given number of clusters. The clustering problem consists of partitioning the data \mathcal{A} into k subsets $\{C^1, C^2, \dots, C^k\}$, called clusters. For each $l = 1, 2, \dots, k$, the cluster C^l is represented by its center $x^l \in \mathbb{R}^n$, and are interested want to determine k cluster centers $\{x^1, x^2, \dots, x^k\}$ such that the sum of certain proximity measures from each point $a^i, i = 1, 2, \dots, m$, to a nearest cluster center x^l is minimized. We define the vector of all centers by $x = (x^1, x^2, \dots, x^k) \in \mathbb{R}^{nk}$.

The clustering problem is given by

$$\min_{x \in \mathbb{R}^{nk}} \left\{ F(x) := \sum_{l=1}^m \min_{1 \leq l \leq k} d(x^l, a^i) \right\}, \quad (1.1)$$

with $d(\cdot, \cdot)$ being a distance-like function.

2 Problem Reformulation and Notations

We begin with a reformulation of the clustering problem which will be the basis for our developments in this work. The reformulation is based on the following fact:

$$\min_{1 \leq l \leq k} u_l = \min \{ \langle u, v \rangle : v \in \Delta \},$$

where Δ denotes the well-known simplex defined by

$$\Delta = \left\{ u \in \mathbb{R}^k \mid \sum_{l=1}^k u_l = 1, u \geq 0 \right\}.$$

Using this fact in Problem (1.1) and introducing new variables $w^i \in \mathbb{R}^k, i = 1, 2, \dots, m$, gives a smooth reformulation of the clustering problem

$$\min_{x \in \mathbb{R}^{nk}} \sum_{i=1}^m \min_{w^i \in \Delta} \langle w^i, d^i(x) \rangle, \quad (2.1)$$

where

$$d^i(x) = (d(x^1, a^i), d(x^2, a^i), \dots, d(x^k, a^i)) \in \mathbb{R}^k, \quad i = 1, 2, \dots, m.$$

Replacing further the constraint $w^i \in \Delta$ by adding the indicator function $\delta_\Delta(\cdot)$, which defined to be 0 in Δ and ∞ otherwise, to the objective function, results in a equivalent formulation

$$\min_{x \in \mathbb{R}^{nk}, w \in \mathbb{R}^{km}} \left\{ \sum_{i=1}^m (\langle w^i, d^i(x) \rangle + \delta_\Delta(w^i)) \right\}, \quad (2.2)$$

where $w = (w^1, w^2, \dots, w^m) \in \mathbb{R}^{km}$. Finally, for the simplicity of the yet to come expositions, we define the following functions

$$H(w, x) := \sum_{i=1}^m H_i(w, x) = \sum_{i=1}^m \langle w^i, d^i(x) \rangle \quad \text{and} \quad G(w) = \sum_{i=1}^m G(w^i) := \sum_{i=1}^m \delta_\Delta(w^i).$$

Replacing the terms in (2.2) with the functions defined above gives a compact equivalent form of the original clustering problem

$$\min \left\{ \Psi(z) := H(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\}. \quad (2.3)$$

3 Clustering via PALM Approach

3.1 Introduction to PALM Theory

Presentation of PALM's requirements and of the algorithm steps ...

3.2 Clustering with PALM for Squared Euclidean Norm Distance Function

In this section we tackle the clustering problem, given in (2.3), with the classical distance function defined by $d(u, v) = \|u - v\|^2$. We devise a PALM-like algorithm, based on the discussion about PALM in the previous subsection. Since the clustering problem has a specific structure, we are ought to exploit it in the following manner.

- (1) The function $w \mapsto H(w, x)$, for fixed x , is linear and therefore there is no need to linearize it as suggested in PALM.
- (2) The function $x \mapsto H(w, x)$, for fixed w , is quadratic and convex. Hence, there is no need to add a proximal term as suggested in PALM.

As in the PALM algorithm, our algorithm is based on alternating minimization, with the following adaptations which are motivated by the observations mentioned above. More precisely, with respect to w we suggest to regularize the subproblem with proximal term as follows:

$$w^i(t+1) = \arg \min_{w^i \in \Delta} \left\{ \langle w^i, d^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i - w^i(t)\|^2 \right\}, \quad i = 1, 2, \dots, m. \quad (3.1)$$

On the other hand, with respect to x we perform exact minimization

$$x(t+1) = \operatorname{argmin} \left\{ H(w(t+1), x) \mid x \in \mathbb{R}^{nk} \right\}. \quad (3.2)$$

It is easy to check that all subproblems, with respect to w^i , $i = 1, 2, \dots, m$, and x , can be simplified as follows:

$$w^i(t+1) = P_{\Delta} \left(w^i(t) - \frac{d^i(x(t))}{\alpha_i(t)} \right), \quad i = 1, 2, \dots, m, \quad (3.3)$$

where P_{Δ} is the orthogonal projection onto the set Δ , and

$$x^l(t+1) = \frac{\sum_{i=1}^m w_l^i(t+1) a^i}{\sum_{i=1}^m w_l^i(t+1)}, \quad l = 1, 2, \dots, k. \quad (3.4)$$

Therefore we can record now the suggested KPALM algorithm.

KPALM

(1) Initialization: $(w(0), x(0)) \in \Delta^m \times \mathbb{R}^{nk}$.

(2) General step ($t = 0, 1, \dots$):

(2.1) Cluster assignment: choose certain $\alpha_i(t) > 0$, $i = 1, 2, \dots, m$, and compute

$$w^i(t+1) = P_\Delta \left(w^i(t) - \frac{d^i(x(t))}{\alpha_i(t)} \right). \quad (3.5)$$

(2.2) Centers update: for each $l = 1, 2, \dots, k$ compute

$$x^l(t+1) = \frac{\sum_{i=1}^m w_l^i(t+1) a^i}{\sum_{i=1}^m w_l^i(t+1)}. \quad (3.6)$$

We begin our analysis of KPALM algorithm with the following boundedness property of the generated sequence. For simplicity, from now on, we denote $z(t) := (w(t), x(t))$, $t \in \mathbb{N}$.

Lemma 3.0.1 (Boundedness of KPALM sequence). *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by KPALM. Then, the following statements hold true.*

(i) For all $l = 1, 2, \dots, k$, the sequence $\{x^l(t)\}_{t \in \mathbb{N}}$ is contained in $\text{Conv}(\mathcal{A})$, the convex hull of \mathcal{A} , and therefore bounded by $M = \max_{1 \leq i \leq m} \|a^i\|$

(ii) The sequence $\{z(t)\}_{t \in \mathbb{N}}$ is bounded in $\mathbb{R}^{km} \times \mathbb{R}^{nk}$.

Proof. (i) Set $\lambda_i = \frac{w_l^i(t)}{\sum_{j=1}^m w_l^j(t)}$, $i = 1, 2, \dots, m$, then $\lambda_i \geq 0$ and $\sum_{i=1}^m \lambda_i = 1$. From (3.4) we have

$$x^l(t) = \frac{\sum_{i=1}^m w_l^i(t) a^i}{\sum_{i=1}^m w_l^i(t)} = \sum_{i=1}^m \left(\frac{w_l^i(t)}{\sum_{j=1}^m w_l^j(t)} \right) a^i = \sum_{i=1}^m \lambda_i a^i \in \text{Conv}(\mathcal{A}). \quad (3.7)$$

Hence $x^l(t)$ is in the convex hull of \mathcal{A} , for all $l = 1, 2, \dots, k$ and $t \in \mathbb{N}$. Taking the norm of $x^l(t)$ and using (3.7) yields that

$$\|x^l(t)\| = \left\| \sum_{i=1}^m \lambda_i a^i \right\| \leq \sum_{i=1}^m \lambda_i \|a^i\| \leq \sum_{i=1}^m \lambda_i \max_{1 \leq i \leq m} \|a^i\| = M.$$

(ii) The sequence $\{w(t)\}_{t \in \mathbb{N}}$ is bounded, since $w^i(t) \in \Delta$ for all $i = 1, 2, \dots, m$ and $t \in \mathbb{N}$. Combined with the previous item, the result follows. \square

The following assumption will be crucial for the coming analysis.

Assumption 1. (i) The chosen sequences of parameters $\{\alpha_i(t)\}_{t \in \mathbb{N}}$, $i = 1, 2, \dots, m$, are bounded, that is, there exist $\underline{\alpha}_i > 0$ and $\overline{\alpha}_i < \infty$ for all $i = 1, 2, \dots, m$, such that

$$\underline{\alpha}_i \leq \alpha_i(t) \leq \overline{\alpha}_i, \quad \forall t \in \mathbb{N}. \quad (3.8)$$

(ii) For all $t \in \mathbb{N}$ there exists $\underline{\beta} > 0$ such that

$$\min_{1 \leq l \leq k} \sum_{i=1}^m w_l^i(t) \geq \underline{\beta}. \quad (3.9)$$

It should be noted that Assumption 1(i) is very mild since the parameters $\alpha_i(t)$, $1 \leq i \leq m$ and $t \in \mathbb{N}$, can be chosen arbitrarily by the user and therefore it can be controlled such that the boundedness property holds true. Assumption 1(ii) is essential since if it is not true then $w_l^i(t) = 0$ for all $1 \leq i \leq m$, which means that the center x^l does not involved in the objective function.

Lemma 3.0.2 (Strong convexity of $H(w, x)$ in x). *The function $x \mapsto H(w, x)$ is strongly convex with parameter $\beta(w) := 2 \min_{1 \leq l \leq k} \left\{ \sum_{i=1}^m w_l^i \right\}$, whenever $\beta(w) > 0$.*

Proof. Since the function $x \mapsto H(w(t), x) = \sum_{l=1}^k \sum_{i=1}^m w_l^i \|x^l - a^i\|^2$ is C^2 , it is strongly convex if and only if the smallest eigenvalue of the corresponding Hessian matrix is positive. Indeed, the Hessian is given by

$$\nabla_{x^j} \nabla_{x^l} H(w, x) = \begin{cases} 0 & \text{if } j \neq l, \quad 1 \leq j, l \leq k, \\ 2 \sum_{i=1}^m w_l^i & \text{if } j = l, \quad 1 \leq j, l \leq k. \end{cases}$$

Since the Hessian is a diagonal matrix, the smallest eigenvalue is $\beta(w) := 2 \min_{1 \leq l \leq k} \sum_{i=1}^m w_l^i$, and the result follows. \square

Now we are ready to prove the decrease property of the KPALM algorithm.

Proposition 3.1 (Sufficient decrease property). *Suppose that Assumption 1 holds true and let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by KPALM. Then, there exists $\rho_1 > 0$ such that*

$$\rho_1 \|z(t+1) - z(t)\|^2 \leq \Psi(z(t)) - \Psi(z(t+1)), \quad \forall t \in \mathbb{N}.$$

Proof. From the step (3.5) we derive the following inequality

$$\begin{aligned} H_i(w(t+1), x(t)) + \frac{\alpha_i(t)}{2} \|w^i(t+1) - w^i(t)\|^2 &= \langle w^i(t+1), d^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i(t+1) - w^i(t)\|^2 \\ &\leq \langle w^i(t), d^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i(t) - w^i(t)\|^2 \\ &= \langle w^i(t), d^i(x(t)) \rangle \\ &= H_i(w(t), x(t)). \end{aligned}$$

Hence, we obtain

$$\frac{\alpha_i(t)}{2} \|w^i(t+1) - w^i(t)\|^2 \leq H_i(w(t), x(t)) - H_i(w(t+1), x(t)). \quad (3.10)$$

Denote $\underline{\alpha} = \min_{1 \leq i \leq m} \alpha_i$. Summing inequality (3.10) over $i = 1, 2, \dots, m$ yields

$$\begin{aligned} \frac{\underline{\alpha}}{2} \|w(t+1) - w(t)\|^2 &= \frac{\underline{\alpha}}{2} \sum_{i=1}^m \|w^i(t+1) - w^i(t)\|^2 \\ &\leq \sum_{i=1}^m \frac{\alpha_i(t)}{2} \|w^i(t+1) - w^i(t)\|^2 \\ &\leq \sum_{i=1}^m [H_i(w(t), x(t)) - H_i(w(t+1), x(t))] \\ &= H(w(t), x(t)) - H(w(t+1), x(t)), \end{aligned}$$

where the first inequality follows from Assumption 1(i).

From Assumption 1(ii) we have that $\beta(w(t)) = 2 \min_{1 \leq l \leq k} \left\{ \sum_{i=1}^m w_l^i(t) \right\} \geq \underline{\beta}$, and from Lemma 3.0.2 it follows that the function $x \mapsto H(w(t), x)$ is strongly convex with parameter $\beta(w(t))$, hence it follows that

$$\begin{aligned} H(w(t+1), x(t)) - H(w(t+1), x(t+1)) &\geq \\ &\geq \langle \nabla_x H(w(t+1), x(t+1)), x(t) - x(t+1) \rangle + \frac{\beta(w(t))}{2} \|x(t) - x(t+1)\|^2 \\ &= \frac{\beta(w(t))}{2} \|x(t+1) - x(t)\|^2 \\ &\geq \frac{\underline{\beta}}{2} \|x(t+1) - x(t)\|^2, \end{aligned}$$

where the equality follows from (3.2), since $\nabla_x H(w(t+1), x(t+1)) = 0$. Set $\rho_1 = \frac{1}{2} \min \{\underline{\alpha}, \underline{\beta}\}$, combined with the previous inequalities, we have

$$\begin{aligned} \rho_1 \|z(t+1) - z(t)\|^2 &= \rho_1 (\|w(t+1) - w(t)\|^2 + \|x(t+1) - x(t)\|^2) \leq \\ &\leq [H(w(t), x(t)) - H(w(t+1), x(t))] + [H(w(t+1), x(t)) - H(w(t+1), x(t+1))] \\ &= H(z(t)) - H(z(t+1)) = \Psi(z(t)) - \Psi(z(t+1)), \end{aligned}$$

where the last equality follows from the fact that $G(w(t)) = 0$ for all $t \in \mathbb{N}$ and therefore $H(z(t)) = \Psi(z(t))$, $t \in \mathbb{N}$. \square

Now, we aim to prove the subgradient lower bound for the iterates gap. The following lemma will be essential in our proof.

Lemma 3.1.1. *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by KPALM, then*

$$\|d^i(x(t+1) - d^i(x(t)))\| \leq 4M \|x(t+1) - x(t)\|, \quad \forall i = 1, 2, \dots, m, t \in \mathbb{N},$$

where $M = \max_{1 \leq i \leq m} \|a^i\|$.

Proof. Since $d(u, v) = \|u - v\|^2$, we get that

$$\begin{aligned}
\|d^i(x(t+1) - d^i(x(t)))\| &= \left[\sum_{l=1}^k \left| \|x^l(t+1) - a^i\|^2 - \|x^l(t) - a^i\|^2 \right|^2 \right]^{\frac{1}{2}} \\
&= \left[\sum_{l=1}^k \left| \|x^l(t+1)\|^2 - 2\langle x^l(t+1), a^i \rangle + \|a^i\|^2 - \|x^l(t)\|^2 + 2\langle x^l(t), a^i \rangle - \|a^i\|^2 \right|^2 \right]^{\frac{1}{2}} \\
&\leq \left[\sum_{l=1}^k \left(\left| \|x^l(t+1)\|^2 - \|x^l(t)\|^2 \right| + \left| 2\langle x^l(t) - x^l(t+1), a^i \rangle \right| \right)^2 \right]^{\frac{1}{2}} \\
&\leq \left[\sum_{l=1}^k \left(\left| \|x^l(t+1)\| - \|x^l(t)\| \right| \cdot \left| \|x^l(t+1)\| + \|x^l(t)\| \right| + 2\|x^l(t) - x^l(t+1)\| \cdot \|a^i\| \right)^2 \right]^{\frac{1}{2}} \\
&\leq \left[\sum_{l=1}^k \left(\|x^l(t+1) - x^l(t)\| \cdot 2M + 2\|x^l(t+1) - x^l(t)\|M \right)^2 \right]^{\frac{1}{2}} \\
&= \left[\sum_{l=1}^k (4M)^2 \|x^l(t+1) - x^l(t)\|^2 \right]^{\frac{1}{2}} = 4M \|x(t+1) - x(t)\|,
\end{aligned}$$

this proves the desired result. \square

Proposition 3.2 (Subgradient lower bound for the iterates gap). *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by KPALM. Then, there exists $\rho_2 > 0$ and $\gamma(t+1) \in \partial\Psi(z(t+1))$ such that*

$$\|\gamma(t+1)\| \leq \rho_2 \|z(t+1) - z(t)\|, \quad \forall t \in \mathbb{N}.$$

Proof. By the definition of Ψ (see (2.3)) we get

$$\partial\Psi = \nabla H + \partial G = \left((\nabla_{w^i} H_i + \partial_{w^i} \delta_\Delta)_{i=1,2,\dots,m}, \nabla_x H \right).$$

Evaluating the last relation at $z(t+1)$ yields

$$\begin{aligned}
\partial\Psi(z(t+1)) &= \\
&= \left((\nabla_{w^i} H_i(w(t+1), x(t+1)) + \partial_{w^i} \delta_\Delta(w^i(t+1)))_{i=1,2,\dots,m}, \nabla_x H(w(t+1), x(t+1)) \right) \\
&= \left((d^i(x(t+1)) + \partial_{w^i} \delta_\Delta(w^i(t+1)))_{i=1,2,\dots,m}, \nabla_x H(w(t+1), x(t+1)) \right) \\
&= \left((d^i(x(t+1)) + \partial_{w^i} \delta_\Delta(w^i(t+1)))_{i=1,2,\dots,m}, \mathbf{0} \right),
\end{aligned}$$

where the last equality follows from (3.6), that is, the optimality condition of $x(t+1)$.

The optimality condition of $w^i(t+1)$ which derived from (3.1), yields that for all $i = 1, 2, \dots, m$ there exists $u^i(t+1) \in \partial\delta_\Delta(w^i(t+1))$ such that

$$d^i(x(t)) + \alpha_i(t) (w^i(t+1) - w^i(t)) + u^i(t+1) = \mathbf{0}. \quad (3.11)$$

Setting $\gamma(t+1) := \left((d^i(x(t+1)) + u^i(t+1))_{i=1,2,\dots,m}, \mathbf{0} \right) \in \partial\Psi(z(t+1))$. Using (3.11) we obtain

$$\gamma(t+1) = \left((d^i(x(t+1)) - d^i(x(t)) - \alpha_i(t)(w^i(t+1) - w^i(t)))_{i=1,2,\dots,m}, \mathbf{0} \right).$$

Hence,

$$\begin{aligned}
\|\gamma(t+1)\| &\leq \sum_{i=1}^m \|d^i(x(t+1)) - d^i(x(t)) - \alpha_i(t)(w^i(t+1) - w^i(t))\| \\
&\leq \sum_{i=1}^m \|d^i(x(t+1)) - d^i(x(t))\| + \sum_{i=1}^m \alpha_i(t) \|w^i(t+1) - w^i(t)\| \\
&\leq \sum_{i=1}^m 4M \|x(t+1) - x(t)\| + m\bar{\alpha} \|z(t+1) - z(t)\| \\
&\leq m(4M + \bar{\alpha}) \|z(t+1) - z(t)\|,
\end{aligned}$$

where the third inequality follows from Lemma 3.1.1, and $\bar{\alpha} = \max_{1 \leq i \leq m} \alpha_i$. Define $\rho_2 = m(4M + \bar{\alpha})$, and the result follows. \square

4 Clustering via Alternation with Weiszfeld Step

4.1 Algorithm to the Smoothed Clustering Problem

In the previous section we showed that Problem (2.1) has the following equivalent form

$$\min \left\{ \Psi(z) := H(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\},$$

where

$$H(w, x) = \sum_{i=1}^m \langle w^i, d^i(x) \rangle = \sum_{i=1}^m \sum_{l=1}^k w_l^i \|x^l - a^i\|,$$

and

$$G(w) = \sum_{i=1}^m \delta_{\Delta}(w^i).$$

In order to be able to use the theory mentioned in Section (3.1), we need the coupled function $H(w, x)$ to be smooth, which is not the case now. Therefore, for any $\varepsilon > 0$, it leads us to the following smoothed form of the clustering problem

$$\min \left\{ \Psi_{\varepsilon}(z) := H_{\varepsilon}(w, x) + G(w) \mid z := (w, x) \in \mathbb{R}^{km} \times \mathbb{R}^{nk} \right\}, \quad (4.1)$$

where

$$H_{\varepsilon}(w, x) = \sum_{i=1}^m \langle w^i, d_{\varepsilon}^i(x) \rangle = \sum_{i=1}^m \sum_{l=1}^k w_l^i \left(\|x^l - a^i\|^2 + \varepsilon^2 \right)^{1/2},$$

and

$$d_{\varepsilon}^i(x) = \left(\left(\|x^1 - a^i\|^2 + \varepsilon^2 \right)^{1/2}, \left(\|x^2 - a^i\|^2 + \varepsilon^2 \right)^{1/2}, \dots, \left(\|x^k - a^i\|^2 + \varepsilon^2 \right)^{1/2} \right) \in \mathbb{R}^k,$$

for all $i = 1, 2, \dots, m$. Note that $\Psi_{\varepsilon}(z)$ is a perturbed form of $\Psi(z)$ for some small $\varepsilon > 0$, and $\Psi_0(z) = \Psi(z)$.

Now we would like to develop an algorithm which is based on the methodology of PALM to solve Problem (4.1). It is easy to see that with respect to w , the objective Ψ_{ε} keeps on the same structure

as Ψ and therefore we apply the same step as in KPALM. More precisely, for all $i = 1, 2, \dots, m$, we have

$$\begin{aligned} w^i(t+1) &= \arg \min_{w^i \in \Delta} \left\{ \langle w^i, d_\varepsilon^i(x(t)) \rangle + \frac{\alpha_i(t)}{2} \|w^i - w^i(t)\|^2 \right\} \\ &= P_\Delta \left(w^i(t) - \frac{d_\varepsilon^i(x(t))}{\alpha_i(t)} \right), \quad \forall t \in \mathbb{N}, \end{aligned}$$

where $\alpha_i(t)$, $i = 1, 2, \dots, m$, is arbitrarily chosen. On the other hand, with respect to x we tackle the subproblem differently than in KPALM. Here we follow exactly the idea of PALM, that is,

$$x^l(t+1) = \operatorname{argmin}_{x^l} \left\{ \left\langle x^l - x^l(t), \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \right\rangle + \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l - x^l(t)\|^2 \right\},$$

where

$$L_\varepsilon^l(w(t+1), x(t)) = \sum_{i=1}^m \frac{w_l^i(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}}, \quad \forall l = 1, 2, \dots, k.$$

Now we present our algorithm for solving Problem (4.1), we call it ε -KPALM. The algorithm alternates between cluster assignment step, similar to that as in KPALM, and centers update step that is based on certain gradient step.

ε -KPALM

(1) Initialization: $(w(0), x(0)) \in \Delta^m \times \mathbb{R}^{nk}$.

(2) General step ($t = 0, 1, \dots$):

(2.1) Cluster assignment: choose certain $\alpha_i(t) > 0$, $i = 1, 2, \dots, m$, and compute

$$w^i(t+1) = P_\Delta \left(w^i(t) - \frac{d_\varepsilon^i(x(t))}{\alpha_i(t)} \right). \quad (4.2)$$

(2.2) Centers update: for each $l = 1, 2, \dots, k$ compute

$$x^l(t+1) = x^l(t) - \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \nabla_{x^l} H_\varepsilon(w(t+1), x(t)). \quad (4.3)$$

Similarly to the KPALM algorithm, the sequence generated by ε -KPALM is also bounded, since here we also have that

$$\begin{aligned} x^l(t+1) &= x^l(t) - \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \nabla_{x^l} H(w(t+1), x(t)) \\ &= x^l(t) - \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \sum_{i=1}^m w_l^i(t+1) \cdot \frac{x^l(t) - a^i}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \\ &= \frac{1}{L_\varepsilon^l(w(t+1), x(t))} \sum_{i=1}^m \frac{w_l^i(t+1) a^i}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \in \operatorname{Conv}(\mathcal{A}). \end{aligned}$$

Before we will be able to prove the two properties needed for global convergence of the sequence $\{z(t)\}_{t \in \mathbb{N}}$ generated by ε -KPALM, we will need several auxiliary results. For the simplicity of the expositions we define the function $f_\varepsilon : \mathbb{R}^n \rightarrow \mathbb{R}$ by

$$f_\varepsilon(x) = \sum_{i=1}^m w_i (\|x - b^i\|^2 + \varepsilon^2)^{1/2},$$

for fixed positive numbers $w_1, w_2, \dots, w_m \in \mathbb{R}$ and $b^i \in \mathbb{R}^n$, $i = 1, 2, \dots, m$. We also need the following auxiliary function $h_\varepsilon : \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ given by

$$h_\varepsilon(x, y) = \sum_{i=1}^m \frac{w_i (\|x - b^i\|^2 + \varepsilon^2)}{(\|y - b^i\|^2 + \varepsilon^2)^{1/2}}.$$

Finally need introduce the following two operators, $T_\varepsilon : \mathbb{R}^n \rightarrow \mathbb{R}^n$ defined by

$$T_\varepsilon(x) = \frac{1}{\sum_{i=1}^m \frac{w_i}{(\|x - b^i\|^2 + \varepsilon^2)^{1/2}}} \sum_{i=1}^m \frac{w_i b^i}{(\|x - b^i\|^2 + \varepsilon^2)^{1/2}},$$

and

$$L_\varepsilon(x) = \sum_{i=1}^m \frac{w_i}{(\|x - b^i\|^2 + \varepsilon^2)^{1/2}}.$$

Lemma 4.0.1 (Properties of the auxiliary function h_ε). *The following properties of h_ε hold.*

(i) For any $y \in \mathbb{R}^n$,

$$h_\varepsilon(y, y) = f_\varepsilon(y).$$

(ii) For any $x, y \in \mathbb{R}^n$,

$$h_\varepsilon(x, y) \geq 2f_\varepsilon(x) - f_\varepsilon(y).$$

(iii) For any $y \in \mathbb{R}^n$,

$$T_\varepsilon(y) = \arg \min_{x \in \mathbb{R}^n} h_\varepsilon(x, y).$$

(iv) For any $x, y \in \mathbb{R}^n$,

$$h_\varepsilon(x, y) = h_\varepsilon(y, y) + \langle \nabla_x h_\varepsilon(y, y), x - y \rangle + L_\varepsilon(y) \|x - y\|^2.$$

Proof. (i) Follows by substituting $x = y$ in $h_\varepsilon(x, y)$.

(ii) For any two numbers $a \in \mathbb{R}$ and $b > 0$ the inequality

$$\frac{a^2}{b} \geq 2a - b,$$

holds true. Thus, for every $i = 1, 2, \dots, m$, we have that

$$\frac{\|x - b^i\|^2 + \varepsilon^2}{(\|y - b^i\|^2 + \varepsilon^2)^{1/2}} \geq 2(\|x - b^i\|^2 + \varepsilon^2)^{1/2} - (\|y - b^i\|^2 + \varepsilon^2)^{1/2}.$$

Multiplying the last inequality by w_i and summing over $i = 1, 2, \dots, m$, the results follows.

- (iii) The function $x \mapsto h_\varepsilon(x, y)$ is strongly convex and its unique minimizer is determined by the optimality equation

$$\nabla_x h_\varepsilon(x, y) = \sum_{i=1}^m \frac{2w_i (x - b^i)}{(\|y - b^i\|^2 + \varepsilon^2)^{1/2}} = 0.$$

Simple algebraic manipulation leads to the relation

$$x = T_\varepsilon(y),$$

and the desired results follows.

- (iv) The function $x \mapsto h_\varepsilon(x, y)$ is quadratic with associated matrix $L_\varepsilon(y)\mathbf{I}$. Therefore, its second-order Taylor expansion around y leads to the desired result. □

Now we can prove that the function f_ε has Lipschitz continuous gradient.

Lemma 4.0.2. *For all $y, z \in \mathbb{R}^n$ the following statement holds true*

$$\|\nabla f_\varepsilon(y) - \nabla f_\varepsilon(z)\| \leq \frac{2L_\varepsilon(z)L_\varepsilon(y)}{L_\varepsilon(z) + L_\varepsilon(y)} \|z - y\|.$$

Proof. Let $z \in \mathbb{R}^n$ be a fixed vector. Define the following two functions

$$\tilde{f}_\varepsilon(y) = f_\varepsilon(y) - \langle \nabla f_\varepsilon(z), y \rangle,$$

and

$$\tilde{h}_\varepsilon(x, y) = h_\varepsilon(x, y) - \langle \nabla f_\varepsilon(z), x \rangle.$$

It is clear that $x \mapsto \tilde{h}_\varepsilon(x, y)$ is also a quadratic function with associated matrix $L_\varepsilon(y)\mathbf{I}$. Therefore, from Lemma 4.0.1(i) we can write

$$\begin{aligned} \tilde{h}_\varepsilon(x, y) &= \tilde{h}_\varepsilon(y, y) + \left\langle \nabla_x \tilde{h}_\varepsilon(y, y), x - y \right\rangle + L_\varepsilon(y) \|x - y\|^2 \\ &= \tilde{f}_\varepsilon(y) + \langle 2\nabla f_\varepsilon(y) - \nabla f_\varepsilon(z), x - y \rangle + L_\varepsilon(y) \|x - y\|^2. \end{aligned} \tag{4.4}$$

On the other hand, from Lemma 4.0.1(ii) we have that

$$\begin{aligned} \tilde{h}_\varepsilon(x, y) &= h_\varepsilon(x, y) - \langle \nabla f_\varepsilon(z), x \rangle \geq 2f_\varepsilon(x) - f_\varepsilon(y) - \langle \nabla f_\varepsilon(z), x \rangle \\ &= 2\tilde{f}_\varepsilon(x) - \tilde{f}_\varepsilon(y) + \langle \nabla f_\varepsilon(z), x - y \rangle, \end{aligned} \tag{4.5}$$

where the last equality follows from the definition of \tilde{f}_ε . Combining (4.4) and (4.5) yields

$$\begin{aligned} 2\tilde{f}_\varepsilon(x) &\leq 2\tilde{f}_\varepsilon(y) + 2\langle \nabla f_\varepsilon(y) - \nabla f_\varepsilon(z), x - y \rangle + L_\varepsilon(y) \|x - y\|^2 \\ &= 2\tilde{f}_\varepsilon(y) + 2\left\langle \nabla \tilde{f}_\varepsilon(y), x - y \right\rangle + L_\varepsilon(y) \|x - y\|^2. \end{aligned}$$

Dividing the last inequality by 2 leads to

$$\tilde{f}_\varepsilon(x) \leq \tilde{f}_\varepsilon(y) + \left\langle \nabla \tilde{f}_\varepsilon(y), x - y \right\rangle + \frac{L_\varepsilon(y)}{2} \|x - y\|^2. \tag{4.6}$$

It is clear that the optimal point of \tilde{f}_ε is z since $\nabla \tilde{f}_\varepsilon(z) = 0$, therefore using (4.6) with $x = y - (1/L_\varepsilon(y)) \nabla f_\varepsilon(y)$ yields

$$\begin{aligned}\tilde{f}_\varepsilon(z) &\leq \tilde{f}_\varepsilon\left(y - \frac{1}{L_\varepsilon(y)} \nabla f_\varepsilon(y)\right) \leq \tilde{f}_\varepsilon(y) + \left\langle \nabla \tilde{f}_\varepsilon(y), -\frac{1}{L_\varepsilon(y)} \nabla f_\varepsilon(y) \right\rangle + \frac{L_\varepsilon(y)}{2} \left\| \frac{1}{L_\varepsilon(y)} \nabla f_\varepsilon(y) \right\|^2 \\ &= \tilde{f}_\varepsilon(y) - \frac{1}{2L_\varepsilon(y)} \left\| \nabla f_\varepsilon(y) \right\|^2.\end{aligned}$$

Thus, using the definition of \tilde{f}_ε and the fact that $\nabla \tilde{f}_\varepsilon(y) = \nabla f_\varepsilon(y) - \nabla f_\varepsilon(z)$, yields that

$$f_\varepsilon(z) \leq f_\varepsilon(y) + \langle \nabla f_\varepsilon(z), z - y \rangle - \frac{1}{2L_\varepsilon(y)} \|\nabla f_\varepsilon(y) - \nabla f_\varepsilon(z)\|^2.$$

Now, following the same arguments we can show that

$$f_\varepsilon(y) \leq f_\varepsilon(z) + \langle \nabla f_\varepsilon(y), y - z \rangle - \frac{1}{2L_\varepsilon(z)} \|\nabla f_\varepsilon(z) - \nabla f_\varepsilon(y)\|^2.$$

Combining the last two inequalities yields that

$$\left(\frac{1}{2L_\varepsilon(z)} + \frac{1}{2L_\varepsilon(y)} \right) \|\nabla f_\varepsilon(y) - \nabla f_\varepsilon(z)\|^2 \leq \langle \nabla f_\varepsilon(z) - \nabla f_\varepsilon(y), z - y \rangle,$$

that is,

$$\|\nabla f_\varepsilon(y) - \nabla f_\varepsilon(z)\| \leq \frac{2L_\varepsilon(z)L_\varepsilon(y)}{L_\varepsilon(z) + L_\varepsilon(y)} \|z - y\|,$$

for all $z, y \in \mathbb{R}^n$. □

The following lemma will be used to prove the sufficient decrease property of the KPALM algorithm.

Lemma 4.0.3. *The following statement holds true.*

$$f_\varepsilon(T_\varepsilon(y)) \leq f_\varepsilon(y) + \langle \nabla f_\varepsilon(y), T_\varepsilon(y) - y \rangle + \frac{L_\varepsilon(y)}{2} \|T_\varepsilon(y) - y\|^2, \quad \forall y \in \mathbb{R}^n.$$

Proof. From Lemma 4.0.1(iv) we have

$$h_\varepsilon(x, y) = h_\varepsilon(y, y) + \langle \nabla_x h_\varepsilon(y, y), x - y \rangle + L_\varepsilon(y) \|x - y\|^2.$$

Lemma 4.0.1(iv) states that $h_\varepsilon(y, y) = f_\varepsilon(y)$ and since $\nabla_x h_\varepsilon(y, y) = 2\nabla f_\varepsilon(y)$ we obtain

$$h_\varepsilon(x, y) = f_\varepsilon(y) + 2 \langle \nabla f_\varepsilon(y), x - y \rangle + L_\varepsilon(y) \|x - y\|^2.$$

Substituting $x = T_\varepsilon(y)$ in the last identity yields

$$h_\varepsilon(T_\varepsilon(y), y) = f_\varepsilon(y) + 2 \langle \nabla f_\varepsilon(y), T_\varepsilon(y) - y \rangle + L_\varepsilon(y) \|T_\varepsilon(y) - y\|^2.$$

Using Lemma 4.0.1(ii) leads to

$$2f_\varepsilon - f_\varepsilon \leq f_\varepsilon(y) + 2 \langle \nabla f_\varepsilon(y), T_\varepsilon(y) - y \rangle + L_\varepsilon(y) \|T_\varepsilon(y) - y\|^2.$$

Rearranging the last inequality yields the desired result. □

Now we get back to ε -KPALM algorithm and prove few technical results about the involved functions which are based on the auxiliary results obtained above.

Proposition 4.1 (Bounds for L_ε^l). *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by ε -KPALM. Then, the following two statements hold true.*

(i) *For all $t \in \mathbb{N}$ and $l = 1, 2, \dots, k$ we have*

$$L_\varepsilon^l(w(t+1), x(t)) \geq \frac{\underline{\beta}}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}},$$

where $d_{\mathcal{A}}$ is the diameter of $\text{Conv}(\mathcal{A})$ and $\underline{\beta}$ is given in (3.9).

(ii) *For all $t \in \mathbb{N}$ and $l = 1, 2, \dots, k$ we have*

$$L_\varepsilon^l(w(t+1), x(t)) \leq \frac{m}{\varepsilon}.$$

Proof. (i) From Assumption 1(ii) and the fact that $x^l(t) \in \text{Conv}(\mathcal{A})$ for all $1 \leq l \leq k$, it follows that

$$L_\varepsilon^l(w(t+1), x(t)) = \sum_{i=1}^m \frac{w_i^l(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \geq \frac{\sum_{i=1}^m w_i^l(t+1)}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}} \geq \frac{\underline{\beta}}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}},$$

as asserted.

(ii) Since $w(t+1) \in \Delta^m$ we have

$$L_\varepsilon^l(w(t+1), x(t)) = \sum_{i=1}^m \frac{w_i^l(t+1)}{(\|x^l(t) - a^i\|^2 + \varepsilon^2)^{1/2}} \leq \sum_{i=1}^m \frac{1}{\varepsilon} = \frac{m}{\varepsilon},$$

as asserted. □

Now we prove the following result.

Proposition 4.2. *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by ε -KPALM. Then, for all $t \in \mathbb{N}$ we have*

$$\begin{aligned} H_\varepsilon(w(t+1), x(t+1)) &\leq H_\varepsilon(w(t+1), x(t)) + \langle \nabla_x H_\varepsilon(w(t+1), x(t)), x(t+1) - x(t) \rangle \\ &\quad + \sum_{l=1}^k \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l(t+1) - x^l(t)\|^2. \end{aligned}$$

Proof. We introduce the following function $H_\varepsilon^l : \mathbb{R}^{km} \times \mathbb{R}^{nk} \rightarrow \mathbb{R}$ defined by

$$H_\varepsilon^l(w, x) = \sum_{i=1}^m w_i^l \left(\|x^l - a^i\|^2 + \varepsilon^2 \right)^{1/2}.$$

Applying Lemma 4.0.3 yields

$$H_\varepsilon^l(w(t+1), x(t+1)) \leq H_\varepsilon^l(x(t)) + \left\langle \nabla_{x^l} H_\varepsilon^l(x(t)), x^l(t+1) - x^l(t) \right\rangle + \frac{L_\varepsilon^l(x(t))}{2} \|x^l(t+1) - x^l(t)\|^2.$$

Summing the last inequality over $l = 1, 2, \dots, k$, and using the fact that $H_\varepsilon(w, x) = \sum_{l=1}^k H_\varepsilon^l(w, x)$ for all $w \in \Delta^m$ and $x \in \mathbb{R}^{nk}$, yields

$$\begin{aligned} H_\varepsilon(w(t+1), x(t+1)) &\leq H_\varepsilon(x(t)) + \sum_{l=1}^k \frac{L_\varepsilon^l(x(t))}{2} \|x^l(t+1) - x^l(t)\|^2 \\ &\quad + \sum_{l=1}^k \left\langle \nabla_{x^l} H_\varepsilon^l(x(t)), x^l(t+1) - x^l(t) \right\rangle. \end{aligned}$$

Replacing the last term with the following compact form

$$\sum_{l=1}^k \left\langle \nabla_{x^l} H_\varepsilon^l(x(t)), x^l(t+1) - x^l(t) \right\rangle = \langle \nabla_x H_\varepsilon(w(t+1), x(t)), x(t+1) - x(t) \rangle,$$

and the result follows. \square

Now we are finally ready to prove the two properties that needed for guaranteeing that the sequence that is generated by ε -KPALM converges to critical point of Ψ_ε .

Proposition 4.3 (Sufficient decrease property). *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by ε -KPALM. Then, there exists $\rho_1 > 0$ such that*

$$\rho_1 \|z(t+1) - z(t)\|^2 \leq \Psi_\varepsilon(z(t)) - \Psi_\varepsilon(z(t+1)) \quad \forall t \in \mathbb{N}.$$

Proof. As we already mentioned the steps of KPALM and ε -KPALM with respect to w are similar and therefore following the same arguments given at the beginning of the proof of Proposition 3.1 we have that

$$\frac{\underline{\alpha}}{2} \|w(t+1) - w(t)\|^2 \leq H_\varepsilon(w(t), x(t)) - H_\varepsilon(w(t+1), x(t)), \quad (4.7)$$

where $\underline{\alpha} = \min_{1 \leq i \leq m} \alpha_i$.

Applying Proposition 4.2 we get for all $t \in \mathbb{N}$ that

$$\begin{aligned} H_\varepsilon(w(t+1), x(t)) - H_\varepsilon(w(t+1), x(t+1)) &\geq \sum_{l=1}^k \frac{L_\varepsilon^l(w(t+1), x(t))}{2} \|x^l(t+1) - x^l(t)\|^2 \\ &\geq \frac{\underline{\beta}}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}} \sum_{l=1}^k \|x^l(t+1) - x^l(t)\|^2 \\ &\geq \frac{\underline{\beta}}{(d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2}} \|x(t+1) - x(t)\|^2, \end{aligned} \quad (4.8)$$

where the last inequality follows from Proposition 4.1(i).

Set $\rho_1 = \frac{1}{2} \min \left\{ \underline{\alpha}, \underline{\beta} / (d_{\mathcal{A}}^2 + \varepsilon^2)^{1/2} \right\}$. Summing (4.7) and (4.8) yields

$$\begin{aligned} \rho_1 \|z(t+1) - z(t)\|^2 &= \rho_1 (\|w(t+1) - w(t)\|^2 + \|x(t+1) - x(t)\|^2) \leq \\ &\leq [H_\varepsilon(w(t), x(t)) - H_\varepsilon(w(t+1), x(t))] + [H_\varepsilon(w(t+1), x(t)) - H_\varepsilon(w(t+1), x(t+1))] \\ &= H_\varepsilon(z(t)) - H_\varepsilon(z(t+1)) = \Psi_\varepsilon(z(t)) - \Psi_\varepsilon(z(t+1)), \end{aligned}$$

where the last equality follows from the fact that $G(w(t)) = 0$, $t \in \mathbb{N}$. This proves the desired result. \square

The next lemma will be useful in proving the subgradient lower bounds for iterates gap property of the sequence generated by ε -KPALM.

Lemma 4.3.1. *For any $x, y \in \mathbb{R}^{nk}$ such that $x^l, y^l \in \text{Conv}(\mathcal{A})$ for all $1 \leq l \leq k$ the following inequality holds*

$$\|d_\varepsilon^i(x) - d_\varepsilon^i(y)\| \leq \frac{d_{\mathcal{A}}}{\varepsilon} \|x - y\|, \quad \forall i = 1, 2, \dots, m,$$

with $d_{\mathcal{A}} = \text{diam}(\text{Conv}(\mathcal{A}))$.

Proof. Define $\psi(t) = \sqrt{t + \varepsilon^2}$, for $t \geq 0$. Using the Lagrange mean value theorem over $a > b \geq 0$ yields

$$\frac{\psi(a) - \psi(b)}{a - b} = \psi'(c) = \frac{1}{2\sqrt{c + \varepsilon^2}} \leq \frac{1}{2\varepsilon},$$

where $c \in (b, a)$. Therefore, for all $i = 1, 2, \dots, m$ and $l = 1, 2, \dots, k$ we have

$$\begin{aligned} \left| \left(\|x^l - a^i\|^2 + \varepsilon^2 \right)^{1/2} - \left(\|y^l - a^i\|^2 + \varepsilon^2 \right)^{1/2} \right| &\leq \frac{1}{2\varepsilon} \left| \|x^l - a^i\|^2 + \varepsilon^2 - (\|y^l - a^i\|^2 + \varepsilon^2) \right| \\ &= \frac{1}{2\varepsilon} \left| \|x^l - a^i\|^2 - \|y^l - a^i\|^2 \right| \\ &= \frac{1}{2\varepsilon} \left| \|x^l - a^i\| + \|y^l - a^i\| \right| \cdot \left| \|x^l - a^i\| - \|y^l - a^i\| \right| \\ &\leq \frac{1}{\varepsilon} d_{\mathcal{A}} \|x^l - y^l\|. \end{aligned}$$

Hence,

$$\begin{aligned} \|d_\varepsilon^i(x) - d_\varepsilon^i(y)\| &= \left[\sum_{l=1}^k \left| \left(\|x - a^i\|^2 + \varepsilon^2 \right)^{1/2} - \left(\|y - a^i\|^2 + \varepsilon^2 \right)^{1/2} \right|^2 \right]^{\frac{1}{2}} \\ &\leq \left[\sum_{l=1}^k \left(\frac{1}{\varepsilon} d_{\mathcal{A}} \|x^l - y^l\| \right)^2 \right]^{\frac{1}{2}} \\ &= \frac{d_{\mathcal{A}}}{\varepsilon} \|x - y\|, \end{aligned}$$

as asserted. \square

Proposition 4.4 (Subgradient lower bound for the iterates gap). *Let $\{z(t)\}_{t \in \mathbb{N}}$ be the sequence generated by ε -KPALM. Then, there exists $\rho_2 > 0$ and $\gamma(t+1) \in \partial \Psi_\varepsilon(z(t+1))$ such that*

$$\|\gamma(t+1)\| \leq \rho_2 \|z(t+1) - z(t)\|, \quad \forall t \in \mathbb{N}.$$

Proof. Repeating the steps of the proof in the case of KPALM yields that

$$\gamma(t+1) := \left((d_\varepsilon^i(x(t+1)) + u^i(t+1))_{i=1,\dots,m}, \nabla_x H_\varepsilon(w(t+1), x(t+1)) \right) \in \partial \Psi_\varepsilon(z(t+1)), \quad (4.9)$$

where for all $1 \leq i \leq m$, $u^i(t+1) \in \partial \delta_\Delta(w^i(t+1))$ such that

$$d_\varepsilon^i(x(t)) + \alpha_i(t) (w^i(t+1) - w^i(t)) + u^i(t+1) = \mathbf{0}. \quad (4.10)$$

Plugging (4.10) into (4.9), and taking norm yields

$$\begin{aligned} \|\gamma(t+1)\| &\leq \sum_{i=1}^m \|d_\varepsilon^i(x(t+1)) - d_\varepsilon^i(x(t)) - \alpha_i(t) (w^i(t+1) - w^i(t))\| \\ &\quad + \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \\ &\leq \sum_{i=1}^m \|d_\varepsilon^i(x(t+1)) - d_\varepsilon^i(x(t))\| + \sum_{i=1}^m \alpha_i(t) \|w^i(t+1) - w^i(t)\| \\ &\quad + \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \\ &\leq \frac{\sqrt{m}d_A}{\varepsilon} \|x(t+1) - x(t)\| + \sqrt{m}\bar{\alpha} \|w(t+1) - w(t)\| + \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\|, \end{aligned}$$

where the last inequality follows from Lemma 4.3.1 and the fact that $\bar{\alpha} = \max_{1 \leq i \leq m} \bar{\alpha}_i$.

Next we bound $\|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \leq c \|x(t+1) - x(t)\|$, for some constant $c > 0$. Indeed, for all $l = 1, 2, \dots, k$, we have

$$\begin{aligned} \nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) &= \nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) - \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \\ &\quad + \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \\ &= \nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) - \nabla_{x^l} H_\varepsilon(w(t+1), x(t)) \\ &\quad + L_\varepsilon^l(w(t+1), x(t)) (x^l(t) - x^l(t+1)), \end{aligned} \quad (4.11)$$

where the last equality follows from (4.3). Therefore,

$$\begin{aligned} \|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| &\leq \sum_{l=1}^k \|\nabla_{x^l} H_\varepsilon(w(t+1), x(t+1))\| \\ &\leq \sum_{l=1}^k L_\varepsilon^l \|x^l(t+1) - x^l(t)\| \\ &\quad + \sum_{l=1}^k \|\nabla_{x^l} H_\varepsilon(w(t+1), x(t+1)) - \nabla_{x^l} H_\varepsilon(w(t+1), x(t))\| \\ &\leq \frac{m}{\varepsilon} \sum_{l=1}^k \|x^l(t+1) - x^l(t)\| + \sum_{l=1}^k \gamma^l(t) \|x^l(t+1) - x^l(t)\|, \end{aligned} \quad (4.12)$$

where the last inequality follows from Proposition 4.1(ii) and Lemma 4.0.2 where

$$\gamma^l(t) = \frac{2L_\varepsilon^l(w(t+1), x(t))L_\varepsilon^l(w(t+1), x(t+1))}{L_\varepsilon^l(w(t+1), x(t)) + L_\varepsilon^l(w(t+1), x(t+1))}, \quad l = 1, 2, \dots, k.$$

From Proposition 4.1(ii) we obtain that

$$\gamma^l(t) = \frac{2}{\frac{1}{L_\varepsilon^l(w(t+1), x(t))} + \frac{1}{L_\varepsilon^l(w(t+1), x(t+1))}} \leq \frac{2}{\frac{\varepsilon}{m} + \frac{\varepsilon}{m}} = \frac{m}{\varepsilon}.$$

Hence, from 4.12, we have

$$\|\nabla_x H_\varepsilon(w(t+1), x(t+1))\| \leq \frac{2m}{\varepsilon} \sum_{l=1}^k \|x^l(t+1) - x^l(t)\| \leq \frac{2m\sqrt{k}}{\varepsilon} \|x(t+1) - x(t)\|.$$

Therefore, setting $\rho_2 = \sqrt{m} \left(\frac{d_A}{\varepsilon} + \bar{\alpha} \right) + \frac{2m\sqrt{k}}{\varepsilon}$, yields and the result. \square

The following lemma shows that the smoothed function $H_\varepsilon(w, x)$ indeed approximates $H(w, x)$.

Lemma 4.4.1 (Closeness of smooth). *For any $(w, x) \in \Delta^m \times \mathbb{R}^{nk}$ and $\varepsilon > 0$ the following inequalities hold true*

$$H(w, x) \leq H_\varepsilon(w, x) \leq H(w, x) + m\varepsilon.$$

Proof. Applying the inequality

$$(a + b)^\lambda \leq a^\lambda + b^\lambda, \quad \forall a, b \geq 0, \lambda \in (0, 1],$$

with $a = \|x^l - a^i\|^2$, $b = \varepsilon^2$ and $\lambda = \frac{1}{2}$, yields

$$\left(\|x^l - a^i\|^2 + \varepsilon^2 \right)^{1/2} \leq \|x^l - a^i\| + \varepsilon, \quad \forall 1 \leq l \leq k, 1 \leq i \leq m.$$

Together with the fact that

$$\|x^l - a^i\| \leq \left(\|x^l - a^i\|^2 + \varepsilon^2 \right)^{1/2},$$

yields the following inequality

$$\|x^l - a^i\| \leq \left(\|x^l - a^i\|^2 + \varepsilon^2 \right)^{1/2} \leq \|x^l - a^i\| + \varepsilon,$$

for all $l = 1, 2, \dots, k$ and $i = 1, 2, \dots, m$. Multiplying each inequality by w_l^i and summing over $l = 1, 2, \dots, k$ and $i = 1, 2, \dots, m$ we obtain

$$H(w, x) \leq H_\varepsilon(w, x) \leq H(w, x) + \sum_{i=1}^m \sum_{l=1}^k w_l^i \varepsilon.$$

Since for all $i = 1, 2, \dots, m$, $w^i \in \Delta$, the result follows. \square

5 Returning to KMENAS

5.1 Similarity to KMEANS

The famous KMEANS algorithm has close proximity to KPALM algorithm. KMEANS alternates between cluster assignments and center updates as well. In detail, we can write its steps in the following manner

- (1) Initialization: Set $t = 0$, and pick random centers $y(0) \in \mathbb{R}^{nk}$.
- (2) For each $t = 0, 1, \dots$ generate a sequence $\{(v(t), y(t))\}_{t \in \mathbb{N}}$ as follows:

- (2.1) Cluster Assignment: For $i = 1, 2, \dots, m$ compute

$$v^i(t+1) = \arg \min_{v^i \in \Delta} \{ \langle v^i, d^i(y(t)) \rangle \}. \quad (5.1)$$

- (2.2) Center Update: For $l = 1, 2, \dots, k$ compute

$$y^l(t+1) = \frac{\sum_{i=1}^m v_l^i(t+1) a^i}{\sum_{i=1}^m v_l^i(t+1)}. \quad (5.2)$$

The KMEANS algorithm obviously resemble KPALM algorithm. Denote $\bar{\alpha}(t) = \max_{1 \leq i \leq m} \alpha_i(t)$. Assuming same starting point $x(0) = y(0)$ and by taking $\bar{\alpha}(t) \rightarrow 0$, we have

$$v(t) = \lim_{\bar{\alpha}(t) \rightarrow 0} w(t), \quad y(t) = \lim_{\bar{\alpha}(t) \rightarrow 0} x(t),$$

meaning, both algorithms converge to the same result.

5.2 KMEANS Convergence Proof

We start with rewriting the KMEANS algorithm, in its most familiar form

KMEANS

- (1) Initialization: $x(0) \in \mathbb{R}^{nk}$.

- (2) General step ($t = 0, 1, \dots$):

- (2.1) Cluster assignment: for $i = 1, 2, \dots, m$ compute

$$C^l(t+1) = \left\{ a \in \mathcal{A} \mid \|a - x^l(t)\| \leq \|a - x^j(t)\|, \quad \forall 1 \leq l \leq k \right\}. \quad (5.3)$$

- (2.2) Centers update: for $l = 1, 2, \dots, k$ compute

$$x^l(t+1) = \text{mean}(C^l(t+1)) := \frac{1}{|C^l(t+1)|} \sum_{a \in C^l(t+1)} a. \quad (5.4)$$

- (2.3) Stopping criteria: halt if

$$\forall 1 \leq l \leq k \quad C^l(t+1) = C^l(t) \quad (5.5)$$

As in KPALM, KMEANS needs Assumption 1(ii) for step (5.4) to be well defined. In order to prove the convergence of KMEANS to local minimum, we will need to following assumption.

Assumption 2. *Let $t \in \mathbb{N}$ be the final iteration of KMEANS run, then we assume that each $a \in \mathcal{A}$ belongs exclusively to single cluster $C^l(t)$.*

For any $x \in \mathbb{R}^{nk}$ we denote the super-partition of \mathcal{A} with respect to x by $\overline{C}^l(x) = \{a \in \mathcal{A} \mid \|a - x^l\| \leq \|a - x^j\|, \forall j \neq l\}$, for all $1 \leq l \leq k$, and the sub-partition of \mathcal{A} by $\underline{C}^l(x) = \{a \in \mathcal{A} \mid \|a - x^l\| < \|a - x^j\|, \forall j \neq l\}$. Moreover, denote $R_{lj}(t) = \min_{a \in C^l(t)} \{\|a - x^j(t)\| - \|a - x^l(t)\|\}$ for all $1 \leq l, j \leq k$, and $r(t) = \min_{l \neq j} R_{lj}$.

Due to Assumption 2 we have that $\overline{C}^l(x(t)) = \underline{C}^l(x(t)) = C^l(t+1)$, for all $1 \leq l \leq k$, $t \in \mathbb{N}$, we also have that $r(t) > 0$ for all $t \in \mathbb{N}$.

Proposition 5.1. *Let $(C(t), x(t))$ be the clusters and centers KMEANS returns. Denote an open neighbourhood of $x(t)$ by $U = B\left(x^1(t), \frac{r(t)}{2}\right) \times B\left(x^2(t), \frac{r(t)}{2}\right) \times \cdots \times B\left(x^k(t), \frac{r(t)}{2}\right)$, then for any $x \in U$ we have $\underline{C}^l(x) = C^l(t)$ for all $1 \leq l \leq k$. Let $(C(t), x(t))$ be the clusters and centers KMEANS returns. Denote by $U = B\left(x^1(t), \frac{r(t)}{2}\right) \times B\left(x^2(t), \frac{r(t)}{2}\right) \times \cdots \times B\left(x^k(t), \frac{r(t)}{2}\right)$ an open neighbourhood of $x(t)$, then for any $x \in U$ we have $C^l(t) = \underline{C}^l(x)$ for all $1 \leq l \leq k$.*

Proof. Pick some $a \in C^l(t)$, then $x^l(t-1)$ is the closest center among the centers of $x(t-1)$. Since KMEANS halts at step t , then from (5.5) we have $x(t) = x(t-1)$, thus $x^l(t)$ is the closest center to a among the centers of $x(t)$. Further we have

$$r(t) \leq \|x^j(t) - a\| - \|x^l(t) - a\| \quad \forall j \neq l. \quad (5.6)$$

Next, we show that $a \in \underline{C}^l(x)$, indeed

$$\begin{aligned} \|a - x^l\| - \|a - x^j\| &\leq \|a - x^l(t)\| + \|x^l(t) - x^l\| - (\|a - x^j(t)\| - \|x^j(t) - x^j\|) \\ &= \|a - x^l\| - \|a - x^j(t)\| + \|x^l(t) - x^l\| + \|x^j(t) - x^j\| \\ &< \|a - x^l\| - \|a - x^j(t)\| + r(t) \\ &\leq -r(t) + r(t) = 0, \end{aligned}$$

where the second inequality holds since $x^l \in B\left(x^l(t), \frac{r(t)}{2}\right)$ and $x^j \in B\left(x^j(t), \frac{r(t)}{2}\right)$, and the third inequality follows from (5.6), and we get that $C^l(t) \subseteq \underline{C}^l(x)$. By definition of $\underline{C}^l(x)$ we have that for any $l \neq j$, $\underline{C}^l(x) \cap \underline{C}^j(x) = \emptyset$, and for all $1 \leq l \leq k$, $\underline{C}^l(x) \subseteq \mathcal{A}$. Now, since $C(t)$ is a partition of \mathcal{A} , then $C^l(t) = \underline{C}^l(x)$ for all $1 \leq l \leq k$. \square

Proposition 5.2 (KMEANS converges to local minimum). *Let $(C(t), x(t))$ be the clusters and centers KMEANS returns, then $x(t)$ is local minimum of F in $U = B\left(x^1(t), \frac{r(t)}{2}\right) \times B\left(x^2(t), \frac{r(t)}{2}\right) \times \cdots \times B\left(x^k(t), \frac{r(t)}{2}\right) \subset \mathbb{R}^{nk}$.*

Proof. The minimum of F in U is

$$\min_{x \in U} F(x) = \min_{x \in U} \sum_{l=1}^k \sum_{a \in C^l(x)} \|a - x^l\|^2 = \min_{x \in U} \sum_{l=1}^k \sum_{a \in C^l(t)} \|a - x^l\|^2,$$

where the last equality follows from Proposition 5.1.

The function $x \mapsto \sum_{l=1}^k \sum_{a \in C^l(t)} \|a - x^l\|^2$ is strictly convex, separable in x^l for all $1 \leq l \leq k$, and reaches its minimum at $\frac{1}{|C^l(t)|} \sum_{a \in C^l(t)} a = \text{mean}(C^l(t)) = x^l(t)$, and the result follows. \square
